# Chapter 5. Blocks, Functions and Reference Variables

Programming Concepts in Scientific Computing EPFL, Master class

October 11, 2023

Syntax

```
{
    // SOME CODE
}
```

Syntax

```
{
  // SOME CODE
}
```

Scope of a variable

```
// Block 1
  int i = 5; // local to Block 1
 // Block 2
   int j = 10; // local to Block 2
   i = 10; // inherited from Block 1
 }
 // variable j is destructed
 j = 5; // so ?
// variable i is destructed
```

#### Scope of a variable

```
Block 1
 int i = 5; // local to Block 1
 // Block 2
   int j = 10; // local to Block 2
   i = 10;  // inherited from Block 1
 // variable j is destructed
 j = 5; // so ?
// variable i is destructed
```

#### Scope of a variable

```
// Block 1
 int i = 5; // local to Block 1
 // Block 2
   int j = 10; // local to Block 2
   i = 10;  // inherited from Block 1
 // variable j is destructed
   i = 5; // so ?
// variable i is destructed
```

```
int i = 5; // global variable
int main() {
 int j = 7; // local variable
 std::cout << i << "\n";
   int i = 10, j = 11;
   std::cout \ll i \ll "\n"; // local value of i is 10
   std::cout << ::i << "\n"; // global value of i is 5
   std::cout << j << "\n"; // value of j here is 11
 }
 std::cout << j << "\n"; // value of j here is 7
 return 0;
```

```
int i = 5; // global variable
int main() {
   int j = 7; // local variable
 std::cout << i << "\n":
   int i = 10, j = 11;
   std::cout << i << "\n"; // local value of i is 10
   std::cout << ::i << "\n"; // global value of i is 5
   std::cout << j << "\n"; // value of j here is 11
 std::cout << j << "\n"; // value of j here is 7
 return 0;
```

# int i = 5; // global variable

```
int main() {
 int j = 7; // local variable
 std::cout << i << "\n";
   int i = 10, j = 11;
   std::cout << i << "\n": // local value of i is 10
   std::cout << ::i << "\n"; // global value of i is 5
   std::cout << j << "\n"; // value of j here is 11
 }
 std::cout << j << "\n"; // value of j here is 7
 return 0;
```

```
int i = 5; // global variable
int main() {
 int j = 7; // local variable
 std::cout << i << "\n";
   int i = 10, j = 11;
       std::cout << i << "\n":
   std::cout << ::i << "\n"; // global value of i is 5
   std::cout << j << "\n"; // value of j here is 11
 }
 std::cout << j << "\n"; // value of j here is 7
 return 0;
```

```
int i = 5; // global variable
int main() {
 int j = 7; // local variable
 std::cout << i << "\n";
   int i = 10, j = 11;
   std::cout << i << "\n"; // local value of i is 10
   std::cout << ::i << "\n"; // global value of i is 5
       std::cout << j << "\n";
 std::cout << j << "\n"; // value of j here is 7
 return 0;
```

```
int i = 5; // global variable
int main() {
  int j = 7; // local variable
  std::cout << i << "\n";
   int i = 10, j = 11;
   std::cout << i << "\n"; // local value of i is 10
   std::cout << ::1 << "\n"; // global value of i is 5
   std::cout << j << "\n"; // value of j here is 11
  }
  std::cout << j << "\n"; // value of j here is 7
 return 0;
```

```
namespace PCSC {
int i = 5; // global variable
}
int main() {
  std::cout << PCSC::i;
  std::cout << std::endl;
}</pre>
```

```
namespace PCSC {
int i = 5; // global variable
}
int main() {
  std::cout << PCSC::i;
  std::cout << std::endl;
}</pre>
```

```
namespace PCSC {
int i = 5; // global variable
}
int main() {
  std::cout << PCSC::i;
  std::cout << std::endl;
}</pre>
```

Simple Functions

#### Declaration/Prototype:

```
double CalculateMinimum(double x, double y);
```

- Function name
- Return type
- Typed parameters

Simple Functions

## Declaration/Prototype:

double CalculateMinimum(double x, double y)

- ► Function name
- Return type
- Typed parameters

Simple Functions

#### Declaration:

double CalculateMinimum(double x, double y);

Simple Functions

```
Declaration:
double CalculateMinimum(double x, double y);
Usage:
   double x = 4.0, y = -8.0;
   double minimum value = CalculateMinimum(x, y);
```

std::cout << "min = " << minimum value << "\n";

Simple Functions

```
Declaration:
double CalculateMinimum(double x, double y);
Usage:
  double x = 4.0, y = -8.0;
  double minimum_value = CalculateMinimum(x, y);
  std::cout << "min = " << minimum value << "\n";
Definition:
double CalculateMinimum(double a, double b) {
  if (a < b) {
    return a;
  return b;
```

Describes how to use a function

- Describes how to use a function
- ▶ Opposed to the function body: implementation

- Describes how to use a function
- ▶ Opposed to the function body: implementation
- ► An interface is usually written in .hh/.hpp (header) files

- Describes how to use a function
- Opposed to the function body: implementation
- ► An interface is usually written in .hh/.hpp (header) files

Why is it important to have this concept?

- Describes how to use a function
- Opposed to the function body: implementation
- ► An interface is usually written in .hh/.hpp (header) files

# Why is it important to have this concept?

- Allow collaborative work
- Normalizes the knowledge needed to call a function
- Limits modifications in cascade

#### Header files

Example: CalculateMinimum.hpp

```
#ifndef CALCULATEMINIMUM_HPP
# define CALCULATEMINIMUM_HPP

double CalculateMinimum(double a, double b);
# endif
```

## Header files

Example: CalculateMinimum.hpp

```
#ifndef CALCULATEMINIMUM_HPP
#define CALCULATEMINIMUM_HPP
```

# double CalculateMinimum(double a

#endif

## Header files

Example: CalculateMinimum.hpp

```
#ifndef calculateminimum_HPP
#define calculateminimum_HPP
double CalculateMinimum(double a, double b);
#endif
```

# Usage

```
#include "calculate_minimum.hpp"
#include <iostream>
int main(int argc, char *argv[]) {
  double x = 4.0, y = -8.0;
  double minimum value = CalculateMinimum(x, y);
  std::cout << "min = " << minimum_value << "\n";</pre>
 return 0;
```

# Usage

```
#include "calculate minimum.hpp"
#include <iostream>
int main(int argc, char *argv[]) {
 double x = 4.0, y = -8.0;
 double minimum value = CalculateMinimum(x,
  std::cout << "min = " << minimum value << "\n";
 return 0;
```

# Implementation file

Example: CalculateMinimum.cpp

```
double CalculateMinimum(double a, double b) {
  if (a < b) {
    return a;
  }
  return b;
}</pre>
```

Returning an array

Return the pointer to the allocated memory!

```
double *allocateVector(int size) {
  double *v = new double[size];
  return v;
}
```

Returning a Matrix

Return the pointer to the allocated memory!

```
double **allocateMatrix(int m, int n) {
  double **mat = new double *[m];
  for (int i = 0; i < m; ++i) {
    mat[i] = new double[n];
  }
  return mat;
}</pre>
```

Input with pointer

```
void assign_by_value(double value) { value = 10; }
void assign_by_pointer(double *value) { *value = 10; }
```

What is the difference?

Input with pointer

```
void assign_by_value(double value) { value = 10; }
void assign_by_pointer(double *value) { *value = 10; }
```

## What is the difference?

- ▶ The difference is the scope (life duration) of the variable value
- Pointer argument allows to change the pointed value
- Non-Pointer arguments are simply copied

Array Input

```
double doIt(double array[]) {
  array[1] = 10.;
  return array[1];
}

double u[10];
  std::cout << doIt(u) << std::endl;
  double *u2 = new double[10];
  std::cout << doIt(u2) << std::endl;</pre>
```

Array Input

```
double doIt(double *array) {
  array[1] = 10.;
  return array[1];
}

double u[10];
  std::cout << doIt(u) << std::endl;
  double *u2 = new double[10];
  std::cout << doIt(u2) << std::endl;</pre>
```

Default parameter value

```
double doIt(double a, double b = 0.) { return a + b; }
```

Default parameter value

```
double doIt(double a, double b = 0.) { return a + b; }
```

```
std::cout << doIt(10., 5.) << std::endl;
```

Default parameter value

```
double doIt(double a, double b = 0.) { return a + b; }
```

```
std::cout << doIt(10., 5.) << std::endl;
std::cout << doIt(10.) << std::endl;</pre>
```

Polymorphism/Overloading

Several functions with the same name:

► They MUST be distinguishable by their arguments(number and types) and return type

Polymorphism/Overloading

Several functions with the same name:

► They MUST be distinguishable by their arguments(number and types) and return type

This is possible

```
double doIt(double a, double b);
double doIt(int a, int b = 0);
```

This is not

Polymorphism/Overloading

Several functions with the same name:

► They **MUST** be distinguishable by their arguments(number and types) and return type

This is possible

```
double doIt(double a, double b);
double doIt(int a, int b = 0);
This is not
double doIt(double a);
int doIt(double a); // not compiling
```

Polymorphism/Overloading

Several functions with the same name:

► They **MUST** be distinguishable by their arguments(number and types) and return type

This is possible

```
double doIt(double a, double b);
double doIt(int a, int b = 0);
This is not
double doIt(double a);
int doIt(double a); // not compiling
int doIt(int a, int b = 0);
int doIt(int a); // not usable
```

#### Recursive Functions

```
int factorial(int a) {
  if (a == 1)
    return 1;
  return a * factorial(a - 1);
}
```

#### Recursive Functions

```
int factorial(int a) {
 if (a == 1)
   return 1;
 return a * factorial(a - 1);
int main() {
 int a = factorial(6);
 return 0;
```

```
The function
```

```
double foo(double a) { return a + 1; }
```

```
The function
double foo(double a) { return a + 1; }
The pointer
  double (*ptr_foo)(double a) = &foo;
```

```
The function
double foo(double a) { return a + 1; }
The pointer
  double (*ptr_foo)(double a) = &foo;
  std::function<double(double a)> ptr_foo_modern = &foo;
```

```
The function
double foo(double a) { return a + 1; }
The pointer
  double (*ptr_foo)(double a) = &foo;
  std::function<double(double a)> ptr_foo_modern = &foo;
The function call
  ptr foo(10);
  ptr_foo_modern(10);
```

A practical syntax of C++: the references void foo(double &a) { a = 10.; }

What is the difference between pointers and references ?

```
int main() {
  int a = 1;
  int &b = a;
  int &c = a;
  int &d = a;
}
```

```
(gdb) x/20xw &a
```

```
int a = 1, b = 2;
int *ptr = &a;
ptr = &b;
int &ref = a;
```

```
int a = 1, b = 2;
int *ptr = &a;
ptr = &b;
int &ref = a;
```

- ▶ The usage: you don't need to use the '\*' operator
- ► A reference points to a value that is 'read only'
- Not possible to change where the reference points to
- Not possible to increment the internal pointer

# References: example of usage

```
Can do the following:
double &getValue(double *A, int ncols, int nrows, //
                  int i, int j) {
 return A[i * ncols + j];
}
Allowing:
  double A[ncols * nrows];
  getValue(A, ncols, nrows, 2, 2) = 10;
```

# References: example of usage

What are the differences between these:

```
void foo ref(const double &ref) {
  std::cout << ref;
  // ref = 2; // can do ?
void foo_val(double val) {
  std::cout << val;
 // val = 2; // can do ?
void foo ptr(const double *ptr) {
  std::cout << ptr;
 // *ptr = 2; // can do ?
```

```
With the function:
void print(double &a) { std::cout << a; }</pre>
You can do:
  double a = 10;
  print(a);
But can you do?:
  print(100);
```

```
A possibility is:

void print(const double &a) { std::cout << a; }

Or the Right reference (R-reference):

void print2(double &&a) { std::cout << a; }
```

The name **Right** and/or **Left** references comes from an assignation statement:

$$\underline{\underline{A}} = \underline{\underline{B} + \underline{C}};$$

The name **Right** and/or **Left** references comes from an assignation statement:

$$\underline{\underline{A}} = \underline{\underline{B} + \underline{C}};$$

- ► Left side: needs memory storage to be decided (by compiler)
- Right side: memory storage is "temporary"

#### Most common usage is:

```
// right reference combined with auto
auto &&a = 100;
auto &&b = a;
```

# Blocks, Functions, References

#### Take away message

- ▶ block/scope: defines the life duration of (static) variables
- ▶ namespace: possibility to name a block (can also be nested)
- ▶ interface concept: Distinguish how to use from implementation
- ▶ Parameters of functions: passed by copy, by pointer or by reference
- Parameters default: example void foo(int a, double b=1.5);
- Overloading: different functions may have the same name (prototype/signature must be different)
- ▶ References: Convenient read only pointer
- ► Left/right References: (Advanced) Convey temporariness to compiler
